# Week 2 Exercises

Patrick Sheehan

March 20, 2024

Please complete all exercises below. You may use stringr, lubridate, or the forcats library.

Place this at the top of your script: library(stringr) library(lubridate) library(forcats)

#### Exercise 1

Read the sales pipe.txt file into an R data frame as sales.

For this exercise I specified the file path where I have the sales\_pipe.txt and loaded it in using the read.delim function.

### Exercise 2

You can extract a vector of columns names from a data frame using the colnames() function. Notice the first column has some odd characters. Change the column name for the FIRST column in the sales date frame to Row ID

Here I called the stringr library and then used colnames() to make the columns into a vector. I then pulled first indice and renamed it to Row.ID.

Note: You will need to assign the first element of colnames to a single character.

```
# Your code here
library(stringr)
colnames(sales)[1] <- 'Row.ID'</pre>
```

### Exercise 3

Convert both Ship.Date and Order.Date to date vectors within the sales data frame. What is the number of days between the most recent order and the oldest order? How many years is that? How many weeks?

Here I used as.Date to convert both the Ship.Date and Order.Date columns into date vectors. I then used the difftime function to subtract the min order date from the max order date to get 1457 days between the most recent and oldest order. I then took this and divided it by dyears/dweeks to get the number of days in years/weeks. 3.989 years and 208.143 weeks.

Note: Use lubridate

```
# Your code here
library(lubridate)
##
## Attaching package: 'lubridate'
## The following objects are masked from 'package:base':
##
##
       date, intersect, setdiff, union
sales$Ship.Date <- as.Date(sales$Ship.Date</pre>
                            , format ='%B %d %Y')
sales$Order.Date <- as.Date(sales$Order.Date</pre>
                            , format= '\m/\%d/\%Y')
difftime(max(sales$Order.Date),min(sales$Order.Date))
## Time difference of 1457 days
difftime(max(sales$Order.Date),min(sales$Order.Date)) / dyears(1) ##Years
## [1] 3.989049
difftime(max(sales$Order.Date),min(sales$Order.Date)) / dweeks(1) ##Weeks
## [1] 208.1429
```

#### Exercise 4

What is the average number of days it takes to ship an order?

Here I took difference between the time it takes to ship by subtracting the order date by the ship date and then took the average of that result. After that I divided it by ddays(1) to get the duration in days instead of seconds.

```
# Your code here
(mean(difftime((sales$Ship.Date),(sales$Order.Date))))/ddays(1)
## [1] 3.908482
```

#### Exercise 5

How many customers have the first name Bill? You will need to split the customer name into first and last name segments and then use a regular expression to match the first name bill. Use the length() function to determine the number of customers with the first name Bill in the sales data.

Here I created a dataframe that showed me all unique customer names. I then used str\_split\_fixed to split the unique\_names and show me only the first name. I then used str\_which to look only for Bill values and used length to determine the number of customers with Bill as their first name.

```
# Your code here
library(stringr)

unique_names <- unique(sales$Customer.Name)
first_name <- str_split_fixed(unique_names, pattern = ' ', n=3)
length(str_which(first_name, "Bill"))</pre>
```

## Exercise 6

How many mentions of the word 'table' are there in the Product.Name column? Note you can do this in one line of code

Here I used str\_which to find the indices of the string table in the Product.Name column of sales. I then used length to get the total number.

```
# Your code here
library(stringr)
length(str_which(sales$Product.Name, 'table'))
```

## [1] 197

## Exercise 7

Create a table of counts for each state in the sales data. The counts table should be ordered alphabetically from A to Z.

Here I used the table function to create a count for each state in the sales data. Before doing this I made the state column into factors so that it would be in alphabetical order.

```
# Your code here
sales$State <- factor(sales$State)
table(sales$State)</pre>
```

##			
##	Alabama	Arizona	Arkansas
##	28	119	22
##	California	Colorado	Connecticut
##	993	90	50
##	Delaware	${\tt District\ of\ Columbia}$	Florida
##	47	1	186
##	Georgia	Idaho	Illinois
##	79	9	286
##	Indiana	Iowa	Kansas
##	74	11	16
##	Kentucky	Louisiana	Maine
##	64	18	4
##	Maryland	Massachusetts	Michigan
##	63	71	142
##	Minnesota	Mississippi	Missouri
##	41	27	37
##	Montana	Nebraska	Nevada
##	2	26	24
##	New Hampshire	New Jersey	New Mexico
##	9	58	11
##	New York	North Carolina	North Dakota
##	555	117	7
##	Ohio	Oklahoma	Oregon
##	211	38	56
##	Pennsylvania	Rhode Island	South Carolina
##	312	25	28
##	South Dakota	Tennessee	Texas

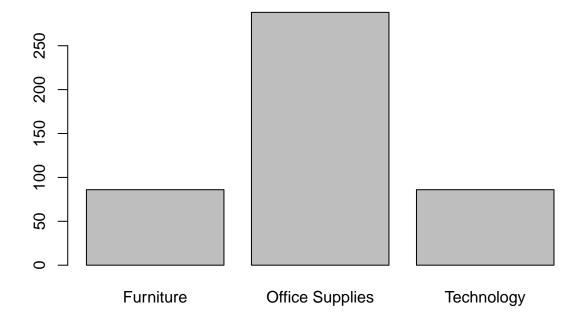

##	9	88	460
##	Utah	Vermont	Virginia
##	27	10	80
##	Washington	West Virginia	Wisconsin
##	254	4	38
##	Wyoming		
##	1		

## Exercise 8

Create an alphabetically ordered barplot for each sales Category in the State of Texas.

Here I created a dataframe that only included the state of texas. I then turned the category column of the texas\_df into a factor so that it would be ordered alphabetically. Lastly I used the table function on the texas\_df category column to be able to use the barplot function and display the number of sales by category in texas.

```
# Your code here
texas_df <- sales[sales$State == 'Texas',]
texas_df$Category <- factor(texas_df$Category)
barplot(table(texas_df$Category))</pre>
```

## Exercise 9

Find the average profit by region. Note: You will need to use the aggregate() function to do this. To understand how the function works type ?aggregate in the console.

Here I used the aggregate function to get the mean of the sales profit categorized by region.

# Exercise 10

Find the average profit by order year. Note: You will need to use the aggregate() function to do this. To understand how the function works type ?aggregate in the console.

Here I used the aggregate function to get the mean of the sales profit categorized by year. I needed to wrap the order date in a year function to show the year and then make it into a list in order to work in the aggregate function.
